For courses in orthopedics, physical therapy, athletic

training, and physical examination, in programs for healthcare providers including physicians, nurses, athletic trainers, physician's assistants, physical therapists, and occupational therapists. This is the field's most comprehensive evidence-based guide to clinical tests for orthopedic physical examination. It presents complete explanations and photography visualizing all commonly used physical exam tests for all body regions, including both neurological screening tools and conventional tests. The quality of research supporting each test is assessed using the QUADAS quality instrument,

which analyzes the extent to which bias may have influenced diagnostic values. Diagnostic values are reported wherever they exist, and summary "Utility" scores are provided for each test based on the authors' interpretation of the research and their use of the tests in clinical practice. This edition adds 200 new tests, presents valuable clusters of tests, and contains two entirely new chapters: one on visceral assessment and medical screening, and another on temporomandibular examination. *Orthopedics of the Upper and Lower Limb*

Angiograms and the Effect on Kidney Function in Orthopedic Trauma Patients We hypothesize that our institution obtains CT angiograms (CTAs) to evaluate for vascular injury more frequently than indicated and that the likelihood of contrast-induced nephropathy (CIN) increases in patients with GFR \leq 60. CTAs are often obtained in lower extremity (LE) trauma to evaluate vascular injury. Commonly accepted indications to obtain CTAs in lower extremity trauma are an ankle-brachial index (ABI) \leq 0.9 or hard signs of vascular injury. There is a paucity of literature regarding risk factors for contrast-induced nephropathy (CIN) following lower extremity CTAs in a

trauma setting. After IRB approval, patients with CTAs following LE trauma were identified using an imaging database between 2010 and 2018. Patients with CTAs following LE trauma with renal function labs were included in the study. Patient charts and imaging were reviewed for demographic data, injuries, kidney function labs, physical exam, treatments, and follow-up. Normality was assessed using Shapiro-Wilk Test and differences between variables were assessed using Wilcoxon Signed Rank Test and Fisher's Exact Test. CTAs were performed on 257 LEs of 199 patients. Of the 257 CTAs, 162 (63%) LE CTAs were not indicated (no hard

signs of vascular injury, ABI0.9). Of the 95 indicated CTAs, 21 (7.4%) limbs had a positive finding on initial CTA (thrombus, occlusion, extravasation, or pseudoaneurysm) concerning for a vascular injury. Of these 21 patients with positive findings, 12 (4.7%) had a lower extremity vascular injury requiring intervention. There was a statistically significant increase in creatinine after obtaining a CTA in these 257 patients ($p=0.010$). Patients with initial GFR60ml/min were more likely to develop AKI compared to patients with GFR60ml/min ($p=0.001$). There was no difference in rate of AKI in patients with a

higher Injury Severity Score (ISS), in both groups of GFR60ml/min ($p=0.15$) or GFR
