Case Studies for Engineers and Scientists John Wiley & Sons

This dissertation addresses the need for multidisciplinary modeling in sustainability applications. Two methods for sustainable assessment, both of which combine mathematical and statistical modeling with life cycle assessment, are developed. Regression streamlining applies linear regression and model cross-validation techniques to streamlined life cycle assessment, resulting in a simple and intuitive way to generate streamlined life cycle inventories as well as estimates of the error in the streamlined inventories relative to a full inventory. The Comprehensive Allocation Investigation Strategy (CAIS) is a calculation procedure for modeling life cycle inventories as functions of allocation decisions. The results can be used to detect situations in which one life cycle appears environmentally superior to another due to allocation decisions rather than differences in the inventories. The final contribution of this dissertation is the process-to-planet (P2P) modeling framework for sustainable engineering applications. Several applications of the P2P framework to engineering design are presented, with the conclusion that the P2P framework results in environmentally superior designs compared to conventional sustainable design methods. The P2P modeling approach also offers an opportunity to integrate fundamental engineering models with macro-economic equilibrium models, allowing engineering and economic policy design problems to be

addressed within the same framework. As a first step towards this integration, a methodology and case study for modeling the effects of an environmental tax policy on a P2P system is presented. Extensions of the existing framework to include partial, general and hybrid equilibrium models are also discussed.
