 Strain Strain is the response of a system to an applied stress. When a material is loaded with a force, it produces a stress, which then causes a material to deform. Engineering strain is defined as the amount of deformation in the direction of the applied force divided by the initial length of the material.

 • Stress and strain: These are size-independent measures of load and displacement, respectively.
 • Elastic behavior: This reversible behavior often shows a linear relation between stress and strain. To minimize deformation, select a material with a large elastic modulus (E or G).

 Engineering Strain. Engineering strain can be defined as the deformation of a material as the result of an applied force or load. This may be the result of static, constant load application and/or from dynamic, variable loading. Several theories or models are used to analyze these deformations.

 Stress-strain analysis (or stress analysis) is an engineering discipline that uses many methods to determine the stresses and strains in materials and structures subjected to forces. In continuum mechanics , stress is a physical quantity that expresses the internal forces that neighboring particles of a continuous material exert on each other, while strain is the measure of the deformation of the material.

Engineers use their understanding of forces, stress, strain and material properties to create safe designs. We have already discussed forces, stress and strain, so that leaves material properties.

Researchers measure properties of materials and how they behave under stress.

The most commonly accepted method in evaluation of the mechanical properties of metals would be the tension test. Its main objective would be to determine the properties relevant to the elastic design of machines and structures. Investigation of the engineering and true Stress-strain relationships of three specimens in conformance with ASTM E 8 - 04 is the aim of this paper.
